Java ; Created by, N/A ; Updated by, N/A. Embedded, EJB, Annotations, XML , EJB, Annotations, XML Object-relational mapping One of the most basic questions about the JVM is: What exactly is an object? In this post I show you how to see the real object with the user interface debugger. What is an object? In Java we have multiple ways to think about the same thing: A value of a certain type, A reference, An object. The distinction between these is subtle. Values are represented in computer memory as bits. Objects are references to a storage location. The Java programming language exposes both types. Both can be used to represent a user, a string, an object, a field or a value. A value can be typed as a String, or a Number. A String is a byte[], and a Number is a int. Both are treated as immutable. - or a. A is a byte[], and a is a. Both are treated as immutable. An object can be cast to any value, for example Number is a subtype of Number. Example: A String is a subtype of String. When you pass a String to a method, the method won't be called on the String object. Instead the JVM will cast the String to a String object and call the method. When you pass a Number to a method, the JVM will cast the Number to a Number object and call the method. Objects are a special type of value in the Java language, but they have a very different meaning. They're a representation of a data structure in the program. A memory location that is referred to by a pointer. An object. An object contains a field and a reference to another object. It can be passed around, but it's nothing more than a reference. How to see an object? In this post we'll talk about how to use the user interface debugger to step into classes, see variables and even edit properties. To better understand what an object looks like, the javac compiler emits an assembler file which contains the object representation. We can view this file with javap, but it's very difficult to understand. Let's make it simpler: jav 82157476af
